

## Appendix 2 – Features of Hypoxia Classification Chart

Hypoxia	Features	Management
No Hypoxia	<ul style="list-style-type: none"> <li>Baseline appropriate for G.A.</li> <li>Normal variability and cycling</li> <li>No repetitive decelerations</li> </ul>	<ul style="list-style-type: none"> <li>Consider whether the CTG needs to continue.</li> <li>If continuing the CTG perform routine hourly review. (see CTG Assessment Tool below)</li> </ul>
<b>Evidence of Hypoxia</b>		
Chronic Hypoxia	<ul style="list-style-type: none"> <li>Higher baseline than expected for G.A.</li> <li>Reduced variability and/ or absence of cycling</li> <li>Absence of accelerations</li> <li>Shallow decelerations</li> <li>Consider the clinical indicators: reduced fetal movements, thick meconium, bleeding,</li> <li>evidence of chorioamnionitis, postmaturity, IUGR</li> </ul>	<ul style="list-style-type: none"> <li>Avoid further stress</li> <li>Expedite birth, if birth is not imminent (consider the whole clinical picture)</li> </ul>
Gradually Evolving Hypoxia	<b>Compensated</b>	<ul style="list-style-type: none"> <li>Likely to respond to conservative interventions (see below)</li> <li>Regular review every 30-60 minutes to assess for signs of further hypoxic change, and that the intervention resulted in an improvement.</li> <li>Other causes such as reduced placental reserve MUST be considered and addressed accordingly.</li> </ul>
	<ul style="list-style-type: none"> <li>Rise in the baseline (with normal variability and stable baseline) preceded by decelerations and loss of accelerations</li> </ul>	
Subacute Hypoxia	<b>Decompensated</b>	<ul style="list-style-type: none"> <li>Needs urgent intervention to reverse the hypoxic insult (remove prostaglandin pessary, stop oxytocin infusion, tocolysis)</li> <li>Birth should be expedited, if no signs of improvement are seen</li> </ul>
	<ul style="list-style-type: none"> <li>Rise in the baseline (with abnormal variability and unstable baseline) preceded by decelerations and loss of accelerations</li> </ul>	
Subacute Hypoxia	<ul style="list-style-type: none"> <li>More time spent during decelerations than at the baseline</li> <li>May be associated with saltatory pattern (increased variability)</li> </ul>	<b>First Stage</b>
		<ul style="list-style-type: none"> <li>Remove prostaglandins/stop oxytocin infusion</li> <li>If no improvement, needs urgent tocolysis</li> <li>If still no evidence of improvement within 10-15 minutes, review situation and expedite birth</li> </ul>
Subacute Hypoxia		<b>Second Stage</b>
		<ul style="list-style-type: none"> <li>Stop maternal active pushing during contractions until improvement is noted.</li> <li>If no improvement is noted, consider tocolysis if birth is not imminent or expedite birth by birth with forceps or ventouse</li> </ul>
Acute Hypoxia	Prolonged Deceleration (> 3 minutes)	<b>Preceded by reduced variability and lack of cycling or reduced variability within the first 3 minutes</b>
		<b>IMMEDIATE DELIVERY IS THE SAFEST OPTION</b>
		<b>Preceded by normal variability and cycling and normal variability during the first 3 minutes of the deceleration (see 3-minute rule above)</b>
		<ul style="list-style-type: none"> <li>Exclude the 3 accidents (i.e. cord prolapse, placental abruption, uterine rupture - if an accident is suspected prepare for immediate birth)</li> <li>Correct reversible causes</li> <li>If no improvement by 9 minutes or any of the accidents diagnosed, immediate birth by the safest and quickest route</li> </ul>

**Unable to Ascertain fetal wellbeing**  
Poor signal quality, uncertain baseline, possible recording of the maternal heart rate)

- Escalate to senior team
- Consider additional Techniques, if appropriate eg.) scalp stimulation, ultrasound scan □ Consider the application of FSE to improve signal quality
